Package ‘catch’

January 4, 2021

Title Covariate-Adjusted Tensor Classification in High-Dimensions

Version 1.0.1

Description Performs classification and variable selection on high-dimensional tensors (multi-dimensional arrays) after adjusting for additional covariates (scalar or vectors) as CATCH model in Pan, Mai and Zhang (2018) <arXiv:1805.04421>. The low-dimensional covariates and the high-dimensional tensors are jointly modeled to predict a categorical outcome in a multi-class discriminant analysis setting. The Covariate-Adjusted Tensor Classification in High-dimensions (CATCH) model is fitted in two steps: (1) adjust for the covariates within each class; and (2) penalized estimation with the adjusted tensor using a cyclic block coordinate descent algorithm. The package can provide a solution path for tuning parameter in the penalized estimation step. Special case of the CATCH model includes linear discriminant analysis model and matrix (or tensor) discriminant analysis without covariates.

adjten

Adjust tensor for covariates.

Description

Adjusts tensor with respect to covariates to achieve a more accurate performance. Tensor depends on the covariates through a linear regression model. The function returns the coefficients of covariates in regression and adjusted tensor list for further classifier modeling. It estimates coefficients based on training data, and then adjusts training tensor. When testing data is provided, the function will automatically adjust testing data by learned coefficients as well.

Usage

adjten(x, z, y, testx = NULL, testz = NULL, is.centered = FALSE)

Arguments

x
Input tensor or matrix list of length N, where N is the number of observations. Each element of the list is a tensor or matrix. The order of tensor can be any integer not less than 2.

z
Input covariate matrix of dimension N x q, where q < N. Each row of z is an observation.

y
Class label vector of dimension N x 1. For K class problems, y takes values in \{1, \ldots, K\}.

testx
Input testing tensor or matrix list. Each element of the list is a test case. When testx is not provided, the function will only adjust training data.

testz
Input testing covariate matrix with each row being an observation.

is.centered
Indicates whether the input tensor and covariates have already been centered by their within class mean or not. If is.centered is FALSE, the function adjten will center data by class. If is.centered is TRUE, the function will skip the centering step.

Details

The model CATCH assumes the linear relationship between covariates and tensor as

\[ X = \mu_k + \alpha \times Z + E, \]

where \( \alpha \) is the matrix of estimated coefficient of covariates. The function removes the effects of covariates on response variable through tensor and obtain \( X - \alpha \times Z \) as adjusted tensor to fit tensor discriminant analysis model.

In estimating \( \alpha \), which is the alpha in the package, adjten first centers both tensor and covariates within their individual classes, then performs tensor response regression which regresses \( X \) on \( Z \).
Value

**gamma**

The estimated coefficients of covariates to plug in classifier. \( \gamma_k \) is a defined function catching of dimension \( q \times (K - 1) \), where \( q \) is the size of covariates and \( K \) is the number of classes.

**xres**

Adjusted training tensor list \( \mathbf{X} - \alpha \overline{\mathbf{X}}_{M+1} \mathbf{Z} \) after adjusting for covariates. The effect of the covariate is removed.

**testxres**

Adjusted testing tensor list \( \mathbf{X} - \alpha \overline{\mathbf{X}}_{M+1} \mathbf{Z} \) after adjusting for covariates. The effect of the covariate is removed.

Examples

```r
n <- 20
p <- 4
k <- 2
nvars <- p*p*p
x <- array(list(),n)
vec_x <- matrix(rnorm(n*nvars),nrow=n,ncol=nvars)
vec_x[1:10,] <- vec_x[1:10,]+2
z <- matrix(rnorm(n*2),nrow=n,ncol=2)
z[1:10,] <- z[1:10,]+0.5
y <- c(rep(1,10),rep(2,10))
for (i in 1:n){
  x[[i]] <- array(vec_x[i,],dim=c(p,p,p))
}
obj <- adjten(x, z, y)
```

catch 3

**catch**

Fit a CATCH model and predict categorical response.
**Description**

The `catch` function solves classification problems and selects variables by fitting a covariate-adjusted tensor classification in high-dimensions (CATCH) model. The input training predictors include two parts: tensor data and low dimensional covariates. The tensor data could be matrix as a special case of tensor. In `catch`, tensor data should be stored in a list form. If the dataset contains no covariate, `catch` can also fit a classifier only based on the tensor predictors. If covariates are provided, the method will adjust tensor for covariates and then fit a classifier based on the adjusted tensor along with the covariates. If users specify testing data at the same time, predicted response will be obtained as well.

**Usage**

```r
catch(x, z = NULL, y, testx = NULL, testz = NULL, nlambda = 100,
lambda.factor = ifelse((nobs - nclass) <= nvars, 0.2, 1E-03),
lambda = NULL, dfmax = nobs, pmax = min(dfmax * 2 + 20, nvars),
pf = rep(1, nvars), eps = 1e-04, maxit = 1e+05, sml = 1e-06,
verbose = FALSE, perturb = NULL)
```

**Arguments**

- `x` Input tensor (or matrix) list of length \( N \), where \( N \) is the number of observations. Each element of the list is a tensor or matrix. The order of tensor can be any positive integer not less than 2.
- `z` Input covariate matrix of dimension \( N \times q \), where \( q < N \). \( z \) can be omitted if covariate is absent.
- `y` Class label. For \( K \) class problems, \( y \) takes values in \{1, \ldots, K\}.
- `testx` Input testing tensor or matrix list. Each element of the list is a test case. When `testx` is not provided, the function will only fit the model and return the classifier. When `testx` is provided, the function will predict response on `testx` as well.
- `testz` Input testing covariate matrix. Can be omitted if covariate is absent. However, training covariates `z` and testing covariates `testz` must be provided or not at the same time.
- `nlambda` The number of tuning values in sequence `lambda`. If users do not specify `lambda` values, the package will generate a solution path containing `nlambda` many tuning values of `lambda`. Default is 100.
- `lambda.factor` When `lambda` is not supplied, `catch` first finds the largest value in `lambda` which yields \( \beta = 0 \). Then the minimum value in `lambda` is obtained by \( \text{(largest value} \times \text{lambda.factor}) \). The sequence of `lambda` is generated by evenly sampling `nlambda` numbers within the range. Default value of `lambda.factor` is 0.2 if \( N < p \) and 0.0001 if \( N > p \).
- `lambda` A sequence of user-specified `lambda` values. `lambda` is the weight of L1 penalty and a smaller `lambda` allows more variables to be nonzero. If NULL, then the algorithm will generate a sequence of `nlambda` many potential `lambda` according to `lambda.factor`. 
**catch**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dfmax</td>
<td>The maximum number of selected variables in the model. Default is the number of observations N.</td>
</tr>
<tr>
<td>pmax</td>
<td>The maximum number of potential selected variables during iteration. In middle step, the algorithm can select at most pmax variables and then shrink part of them such that the number of final selected variables is less than dfmax. Default is ( \min(dfmax \times 2 + 20, N) ).</td>
</tr>
<tr>
<td>pf</td>
<td>Weight of lasso penalty. Default is a vector of value 1 and length p, representing L1 penalty of length p. Can be modified to use adaptive lasso penalty.</td>
</tr>
<tr>

<td>Convergence threshold for coordinate descent difference between iterations. Default value is ( 1e^{-04} ).</td>
</tr>
<tr>
<td>maxit</td>
<td>Maximum iteration times for all lambda. Default value is ( 1e+05 ).</td>
</tr>
<tr>
<td>sml</td>
<td>Threshold for ratio of loss function change after each iteration to old loss function value. Default value is ( 1e^{-06} ).</td>
</tr>
<tr>
<td>verbose</td>
<td>Indicates whether print out lambda during iteration or not. Default value is FALSE.</td>
</tr>
<tr>
<td>perturb</td>
<td>Perturbation scaler. If it is specified, the value will be added to diagonal of estimated covariance matrix. A small value can be used to accelerate iteration. Default value is NULL.</td>
</tr>
</tbody>
</table>

**Details**

The **catch** function fits a linear discriminant analysis model as follows:

\[
Z|\{Y = k\} \sim N(\phi_k, \psi),
\]

\[
X|\{Z = z, Y = k\} \sim TN(\mu_k + \alpha \times M+1 \times Z, \Sigma_1, \ldots, \Sigma_M).
\]

The categorical response is predicted from the estimated Bayes rule:

\[
\hat{Y} = \arg \max_{k=1,\ldots,K} \left( a_k + \gamma_k^T Z + \beta_k^T X - \alpha \times M+1 \times Z \right),
\]

where \( X \) is the tensor, \( Z \) is the covariates, \( a_k, \gamma_k \) and \( \alpha \) are parameters estimated by CATCH. A detailed explanation can be found in reference. When \( Z \) is not NULL, the function will first adjust tensor on covariates by modeling

\[
X = \mu_k + \alpha \times M+1 \times Z + E,
\]

where \( E \) is an unobservable tensor normal error independent of \( Z \). Then **catch** fits model on the adjusted training tensor \( X - \alpha \times M+1 \times Z \) and makes predictions on testing data by using the adjusted tensor list. If \( Z \) is NULL, it reduces to a simple tensor discriminant analysis model.

The coefficient of tensor \( \beta \), represented by \texttt{beta} in package, is estimated by

\[
\min_{\beta_2,\ldots,\beta_K} \left\{ \sum_{k=2}^{K} \left( \langle \beta_k, [\beta_k; \tilde{\Sigma}_1, \ldots, \tilde{\Sigma}_M] \rangle - 2 \langle \beta_k, \hat{\mu}_k - \bar{\mu}_1 \rangle \right) + \lambda \sum_{j_1,\ldots,j_M} \sqrt{\sum_{k=2}^{K} \beta_{k,j_1,\ldots,j_M}^2} \right\}.
\]

When response is multi-class, the group lasso penalty over categories is added to objective function through parameter lambda, and it reduces to a lasso penalty in binary problems.

The function **catch** will predict categorical response when testing data is provided. If testing data is not provided or if one wishes to perform prediction separately, **catch** can be used to only fit model with a catch object outcome. The object outcome can be combined with the adjusted tensor list from **adjten** to perform prediction by **predict.catch**.
Value

beta Output variable coefficients for each lambda, which is the estimation of \( \beta \) in the Bayes rule. beta is a list of length being the number of lambdas. Each element of beta is a matrix of dimension \( nvars \times (nclass - 1) \).

df The number of nonzero variables for each value in sequence lambda.

dim Dimension of coefficient array.

lambda The actual lambda sequence used. The user specified sequence or automatically generated sequence could be truncated by constraints on dfmax and pmax.

obj Objective function value for each value in sequence lambda.

x The tensor list after adjustment in training data. If covariate is absent, this is the original input tensor list.

y Class label in training data.

npasses Total number of iterations.

jerr Error flag.

sigma Estimated covariance matrix on each mode. sigma is a list with the ith element being covariance matrix on ith mode.

delta Estimated delta matrix \( \text{vec}(\hat{\mu}_2 - \hat{\mu}_1), \cdots, \text{vec}(\hat{\mu}_K - \hat{\mu}_1) \).

mu Estimated mean array of X.

prior Proportion of samples in each class.

call The call that produces this object.

pred Predicted categorical response for each value in sequence lambda when testx is provided.

catch_matrix  

**Fit a CATCH model for matrix and predict categorical response.**

**Description**

Fits a classifier for matrix data. catch_matrix is a special case of catch when each observation $X_i$ is a matrix. Different from catch takes list as input, data need to be formed in an array to call the function (see arguments). The function will perform prediction as well.

**Usage**

catch_matrix(x, z = NULL, y, testx = NULL, testz = NULL, ...)

**Arguments**

- **x**  
  Input matrix array. The array should be organized with dimension $p_1 \times p_2 \times N$.

- **z**  
  Input covariate matrix of dimension $N \times q$, where $q < N$. z can be omitted if covariate is absent.

- **y**  
  Class label. For $K$ class problems, y takes values in $\{1, \ldots, K\}$.

- **testx**  
  Input testing matrix array. When testx is not provided, the function will only fit model. When testx is provided, the function will predict response on testx as well.

- **testz**  
  Input testing covariate matrix. Can be omitted if there is no covariate.

- **...**  
  Other arguments that can be passed to catch.

**Details**

The function fits a matrix classifier as a special case of catch. The fitted model and predictions should be identical to catch when matrix data is provided. Input matrix should be organized as three-way array where sample size is the last dimension. If the matrix is organized in a list, users can either reorganize it or use catch directly to fit model, which takes a matrix or tensor list as input and has the same output as catch_matrix.
Value

beta  Output variable coefficients for each lambda. beta is a list of length being the number of lambdas. Each element of beta is a matrix of dimension \((p_1 \times p_2) \times (nclass - 1)\).

df  The number of nonzero variables for each value in sequence lambda.

dim  Dimension of coefficient array.

lambda  The actual lambda sequence used. The user specified sequence or automatically generated sequence could be truncated by constraints on dfmax and pmax.

obj  Objective function value for each value in sequence lambda.

x  The matrix list after adjustment in training data. If covariate is absent, this is the original input matrix.

y  Class label in training data.

npasses  Total number of iterations.

jerr  Error flag.

sigma  Estimated covariance matrix on each mode. sigma is a list with the ith element being covariance matrix on ith mode.

delta  Estimated delta matrix \((vec(\hat{\mu}_2 - \hat{\mu}_1), \cdots, vec(\hat{\mu}_K - \hat{\mu}_1))\).

mu  Estimated mean array.

prior  Prior proportion of observations in each class.

call  The call that produces this object.

pred  Predicted categorical response for each value in sequence lambda when testx is provided.

csa  

**Colorimetric sensor array (CSA) data**

**Description**

A dataset collected from a series of CSA experiments to identify volatile chemical toxicants (VCT). Chemical dyes were exposed to VCT under different concentration conditions and colors of dyes were recorded to identify the class of VCT. There are two concentration conditions PEL (permissible exposure level) and IDLH (immediately dangerous to life of health).

**Usage**

data(csa)

**Format**

Two lists, *PEL* and *IDLH*, and a numeric vector *y*. Each list contains 147 matrices of dimension 36 × 3.

*PEL*  A list of matrices containing the observations after exposure at PEL.

*IDLH*  A list of matrices containing the observations after exposure at IDLH level.

*y*  Class label ranging from 1 to 21.

**Details**

This dataset is provided in the Supplementary material of Zhong (2015). In each concentration case, there are 147 observations and 21 classes. We reorganize the data into a list to be directly called by catch. For matrices in the list, each row represents a dye and the three columns correspond to red, green and blue.

**Source**

**cv.catch**  
*Cross-validation for CATCH*

**Description**
Performs k-fold cross validation for CATCH and returns the best tuning parameter $\lambda$ in the user-specified or automatically generated choices.

**Usage**
```
cv.catch(x, z = NULL, y, nfolds = 5, lambda = NULL, lambda.opt = "min", ...)```

**Arguments**
- **x**: Input tensor or matrix list of length $N$, where $N$ is the number of observations. Each element of the list is a tensor or matrix. The order of tensor can be any number and not limited to three.
- **z**: Input covariate matrix of dimension $N \times q$, where $q < N$. $z$ can be omitted if covariate is absent.
- **y**: Class label. For $K$ class problems, $y$ takes values in $\{1, \ldots, K\}$.
- **nfolds**: Number of folds. Default value is 5.
- **lambda**: User-specified $\lambda$ sequence for cross validation. If not specified, the algorithm will generate a sequence of $\lambda$s based on all data and cross validate on the sequence.
- **lambda.opt**: The optimal criteria when multiple elements in $\lambda$ return the same minimum classification error. "min" will return the smallest $\lambda$ with minimum cross validation error. "max" will return the largest $\lambda$ with the minimum cross validation error.
- **...**: Other arguments that can be passed to `catch`.

**Details**
The function `cv.catch` runs function `catch` nfolds+1 times. The first one fits model on all data. If lambda is specified, it will check if all lambda satisfies the constraints of dfmax and pmax in `catch`. If not, a lambda sequence will be generated according to lambda.factor in `catch`. Then the rest nfolds many replicates will fit model on nfolds-1 many folds data and predict on the omitted fold, respectively. Return the lambda with minimum average cross validation error and the largest lambda within one standard error of the minimum.

**Value**
- **lambda**: The actual lambda sequence used. The user specified sequence or automatically generated sequence could be truncated by constraints on dfmax and pmax.
- **cvm**: The mean of cross validation errors for each lambda.
The standard error of cross validation errors for each lambda.

lambda.min
The lambda with minimum cross validation error. If lambda.opt is min, then returns the smallest lambda with minimum cross validation error. If lambda.opt is max, then returns the largest lambda with minimum cross validation error.

lambda.1se
The largest lambda with cross validation error within one standard error of the minimum.

catch.fit
The fitted catchobj object.

}
objcv <- cv.catch(x, z, y=y)

predict.catch
Predict categorical responses.

Description
Predict categorical responses on new data given the fitted model input.

Usage

## S3 method for class 'catch'
predict(object, newx, z = NULL, ztest = NULL, gamma = NULL, ...)

**Arguments**

- **object**: Input catchobj class object as fitted model.
- **newx**: Input adjusted testing tensor or matrix list. Each element of the list is a tensor. The tensor should of the same dimension as training data.
- **z**: Input training covariates matrix. z can be omitted if there is no covariate.
- **ztest**: Input testing covariates matrix. ztest can be omitted if there is no covariate.
- **gamma**: Coefficients of covariates obtained from adjten. gamma is NULL if there is no covariate.
- **...**: Other arguments that can be passed to predict.

**Details**

The function fits LDA model on selected discriminant vectors. Call predict or predict.catch to perform predictions.

There are two ways to make predictions. One way is to directly predict at the same time as fitting model by catch since predict.catch has already been embedded in catch and it will predicts response when testing data is provided. The other way is to first use adjten to adjuste tensor and catch to fit model. predict.catch will take the input adjusted tensor list newx, covariate coefficient gamma from adjten and the fitted model from catch to perform prediction. The prediction is identical to providing catch testing data.

**Value**

- **pred**: Predicted response of newx for each lambda in model object.
